CRACKED TOOTH SYNDROME

Dr Vijay Salvi

We all come across apparently healthy teeth eliciting complex and often bizarre symptoms. The patient will give a long history of undiagnosed but severe pain, and of treatments which failed to provide relief. These symptoms can be attributed to a “cracked” tooth.

This article describes the signs and symptoms, diagnostic techniques, classification and management to what is universally referred to as “Cracked Tooth Syndrome”. The article will describe those cracks that may have involved the underlying dentin and has the potential to propagate further to the pulp and/or periodontal structure culminating in a fractured tooth but will not refer to superficial enamel cracks which may be secondary to trauma, stress or iatrogenic in nature.

People are living longer and keeping their teeth longer. As a result, patients are more likely to have complex restorative and endodontic procedures leaving teeth more susceptible to cracks. Stressful lifestyle resulting in parafunctional habits such as clenching and bruxism and consumption of paan, betel nut etc. are important contributory factors. Additionally, in recent years, practitioners have been more aware of the existence of cracks and, therefore, diagnose more cracks.

The key to saving a cracked tooth is to be aware of the characteristic signs and symptoms, diagnose the crack as early in its development as possible and initiate appropriate treatment without delay.

CLASSIC SIGNS, CLASSIC CONFUSION

Teeth with cracks elicit erratic pain on mastication, especially with release of biting pressure and/or pain to extremes of temperature, especially cold. Generally, there is no pain to percussion, and radiographs are inconclusive. Often patients give history of pain which has been difficult to diagnose and of treatment/s which has failed to relieve their symptoms. Depending on the location, direction, and extent of the crack, the patient may present any one or all of these signs and symptoms making diagnosis confusing.

If the pulp is involved, there may be signs and symptoms of irreversible pulpitis or necrosis with periradicular pathosis. If the crack extends to a root surface, there may be a periodontal defect.

Many times, cracks go unnoticed until a variety of symptoms are present, a restoration is removed, or a significant periodontal defect is identified. If caught and treated appropriately, many cracks can be stopped or at least slowed down from propagating further, preventing loss of the tooth. Steps should be taken immediately to confirm the presence of a crack, determine the type of crack, and formulate an appropriate treatment plan.

DIAGNOSTIC PROTOCOL FOR DETECTION OF CRACKS:

In a tooth suspected of having a crack it is important to know if the tooth has undergone endodontic procedure. A cracked root canaled tooth will exhibit only those signs and symptoms associated with periodontal breakdown secondary to crack propagation. Teeth with vital pulp will require further investigations to determine the health of pulp and periodontium once a crack is diagnosed.
